Mathematical Statistics I

Chapter 3: Joint Distributions

Jesse Wheeler

Outline

Introduction

Introduction

- This material is based on the textbook by Rice (2007, Chapter 3).

- Our goal is to better understand the joint probability structure of more than one random variable, defined on the same sample space.

- One reason that studying joint probabilities is an important topic is that it enables us to use what we know about one variable to study another.

Joint cdf

- Just like the univariate case, the joint behavior of two random variables, X and Y, is determined by the cumulative distribution function

$$F(x,y) = P(X \leq x, Y \leq y).$$

- This is true for both discrete and continuous random variables.
- The any set $A \subset \mathbb{R}^2$, the joint cdf can give $P\big((X,Y) \in A\big)$.

Joint cdf II

- For example, let A be the rectangle defined by $x_1 < X < x_2$, and $y_1 < Y < y_2$. (It helps to draw a picture...)
- $F(x_2, y_2)$ gives $P(X < x_2, Y < y_2)$, an area that is too big, so we subtract off pieces
    - $F(x_2, y_1) = P(X < x_2, Y < y_1)$ (we already have the area $X < x_2$, but now subtract away the area $Y < y_1$).
    - $F(x_1, y_2) = P(X < x_1, Y < y_2)$ (Now subtracting the area $X < x_1$)
    - We have "double subtracted" the area $\{X < x_1, Y < y_1\}$, so we add it back.

$$P\big((X, Y) \in A\big) = F(x_2, y_2) - F(x_2, y_1) - F(x_1, y_2) + F(x_1, y_1).$$

Joint cdf III

- The definition also applies to more than two random variables.

- Let $X_1, \ldots, X_n$ be jointly distributed random variables defined on the same sample space. Then

$$F(x_1, x_2, \ldots, x_n) = P(X_1 \leq x_1, X_2 \leq x_2, \ldots, X_n \leq x_n).$$

- Like the univariate case, we can also define the pmf and pdf of jointly distributed random variables as well.

Discrete Random Variables

Discrete Random Variables

Definition: Joint pmf

Let X and Y be discrete random variables define on the same sample space, and take on values $x_1, x_2, \ldots$ and $y_1, y_2, \ldots$, respectively. The joint pmf (or joint frequency function), is

$$p(x_i, y_j) = P(X = x_i, Y = y_j).$$

- For discrete RVs, it's often useful to describe the joint pmf as a frequency table.

Discrete Random Variables II

- Suppose a fair coin is tossed 3 times. Let X denote the number of heads on the first toss, and Y the total number of heads.

- The sample space is

$$\Omega = \{hhh, hht, hth, thh, htt, tht, tth, ttt\}.$$

- The joint pmf can be expressed as the frequency table below (Table 1).

Discrete Random Variables III

	y			
x	0	1	2	3
0	$\frac{1}{8}$	$\frac{2}{8}$	$\frac{1}{8}$	0
1	0	$\frac{1}{8}$	$\frac{2}{8}$	$\frac{1}{8}$

Table 1: Frequency table for X and Y, flipping a fair coin three times.

- Note that the probabilities in Table 1 sum to one.
- Using the probability laws we have already learned, we can calculate marginal probabilities.

$$\begin{aligned}
p_Y(0) &= P(Y = 0) \\
&= P(Y = 0, X = 0) + P(Y = 0, X = 1) \\
&= \frac{1}{8} + 0 = \frac{1}{8} \\
p_Y(1) &= P(Y = 1) \\
&= P(Y = 1, X = 0) + P(Y = 1, X = 1) \\
&= \frac{2}{8} + \frac{1}{8} = \frac{3}{8}.
\end{aligned}$$

Discrete Random Variables V

- In general, to find the frequency function for Y and X, we just need to sum the appropriate columns or rows, respectively.

- $p_X(x) = \sum_i P(x, y_i)$ and $p_Y(y) = \sum_j P(x_j, y)$.

- The case with multiple random variables is similar:

$$p_{X_i}(x_i) = \sum_{x_j : j \neq i} p(x_1, x_2, \ldots, x_n).$$

- We can also get marginal frequencies for more than one variable:

$$p_{X_i X_j}(x_i, x_j) = \sum_{x_k : k \notin \{i, j\}} p(x_1, x_2, \ldots, x_n).$$

Example: Multinomial Distribution

- The multinomial distribution is a generalization of the binomial distribution.
- Suppose there are n independent trials, each with r possible outcomes, with probabilities $p_1, p_2, \ldots, p_r$, respectively.
- Let N_i be the total number of outcomes of type i in the n trials, with $i \in \{1, 2, \ldots, r\}$.
- The probability of any particular sequence $(N_1, N_2, \ldots, N_r) = (n_1, n_2, \ldots, n_r)$ is

$$p_1^{n_1} p_2^{n_2} \cdots p_r^{n_r}$$

Example: Multinomial Distribution II

- The total number of ways to do this was an identity from Chapter 1 (Proposition 1.3):

$$\binom{n}{n_1 \cdots n_r}.$$

- Combining this gives us the pmf of the multinomial distribution:

Multinomial Distribution

Let $N_1, N_2, \ldots, N_r$ be random variables that follow a multinomial distribution with parameters N and $(p_1, \ldots, p_r)$. The joint pmf is

$$p(n_1, n_2, \ldots, n_r) = \binom{n}{n_1 \cdots n_r} p_1^{n_1} p_2^{n_2} \cdots p_r^{n_r}$$

Example: Multinomial Distribution III

- The marginal distribution for any N_i can be found by summing the joint frequency function over the other n_j.

- While possible, this is a non-trivial algebraic exercise.

- The simple alternative is to reframe the problem: Let N_i be the number of successes in n trials, and $\tilde{N}_i = \sum_{j \neq i} N_j$ be the number of failures. The probability of success is still p_i, leaving the probability of failure to be $1 - p_i$.

- Thus, we see that the marginal distribution for N_i must follow a binomial distribution:

$$p_{N_i}(n_i) = \sum_{n_j : j \neq i} \binom{n}{n_1 \cdots n_r} p_1^{n_1} p_2^{n_2} \cdots p_r^{n_r}$$

$$= \binom{n}{n_i} p_i^{n_i} (1 - p_i)^{n - n_i}$$

Continuous Random Variables

Continuous Random Variables

- Let X, Y be continuous random variables with joint cdf $F(x, y)$.

- Their joint density function is a piecewise continuous function of two variables, $f(x, y)$.

- A few properties:
  - $f(x, y) \geq 0$ for all $(x, y) \in \mathbb{R}$ (or the support).
  - $\int_{-\infty}^{\infty} \int_{-\infty}^{\infty} f(x, y) dx dy = 1$.
  - For any "measureable set" $A \subset \mathbb{R}^2$,
    $P((X, Y) \in A) = \int \int_A f(x, y) dx dy$
  - In particular, $F(x, y) = \int_{-\infty}^{x} \int_{-\infty}^{y} f(u, v) du dv$.

Continuous Random Variables II

- From the fundamental theorem of multivariable calculus, it follows that

$$f(x,y) = \frac{\partial^2}{\partial x \partial y} F(x,y),$$

  wherever the derivative is defined.

Continuous Random Variables III

Finding joint probabilities

Let X, Y be jointly defined RVs with pdf

$$f(x, y) = \frac{12}{7}(x^2 + xy), \quad 0 \le x \le 1, \quad 0 \le y \le 1.$$

Find $P(X > y)$.

Solution:

Marginal cdf

The marginal cdf of X, denoted F_X, is

$$F_X(x) = P(X \leq x)$$
$$= P(X \leq x \cap Y \in \mathbb{R}) = P(X \leq x \cap Y < \infty)$$
$$= \lim_{y \to \infty} F(x, y)$$
$$= \int_{-\infty}^{x} \int_{-\infty}^{\infty} f(u, y) dy du.$$

By taking the derivative of both sides of the equation, we get the marginal density of X:

$$f_X(x) = F_X'(x) = \int_{-\infty}^{\infty} f(x, y) dy.$$

Marginal cdf II

Calculating Marginal Densities

Using the same joint distribution as the previous example, find the marginal density of X:

$$\begin{aligned}
f_X(x) &= \int_Y f(x,y)dy \\
&= \frac{12}{7} \int_0^1 (x^2 + xy)dy \\
&= \frac{12}{7} \Big(x^2 y + \frac{x}{2}y^2\Big)\Big|_0^1 \\
&= \frac{12}{7} \Big(x^2 + \frac{x}{2}\Big)
\end{aligned}$$
